Attribute-based Encryption (ABE)

- Introduced by Sahai and Waters in 2005 as a generalization of IBE;
- Two forms of ABE:
 - Key-policy ABE (KP-ABE);
 - Ciphertext-policy ABE (CP-ABE);
- Known constructions:
 - based on secret sharing and just one bilinear map;
 - based on leveled multi-linear maps;
 - based on lattices and the LWE problem.

Key-policy Attribute-based Encryption (KP-ABE)

A KP-ABE scheme consists of four algorithms:

$Setup(\lambda)$: PPT alg.: outputs public parameters PP and master key MSK ;

$Enc(m, A, PP)$: PPT alg.: encrypts message m with attributes $A \subseteq \mathcal{U}$;

$KeyGen(\mathcal{C}, MSK)$: PPT alg.: outputs decryption key for access structure \mathcal{C} ;

$Dec(E, D)$: DPT alg.: decrypts E with D and outputs a message or the special symbol \perp .

Correctness property:

$$E \leftarrow Enc(m, A, PP), \mathcal{C}(A) = 1, D \leftarrow KeyGen(\mathcal{C}, MSK) \Rightarrow m = Dec(E, D)$$

Secret Sharing and KP-ABE

V. Goyal et al.: *Attribute-based Encryption for Fine-grained Access Control of Encrypted Data*, CCS 2006

For n attributes $1, \dots, n$:

$$\text{Setup}(\lambda): y, t_1, \dots, t_n \leftarrow \mathbb{Z}_p, \text{MSK} = (y, t_1, \dots, t_n) \\ PP = (p, G_1, G_2, g, e, n, Y = e(g, g)^y, (T_i = g^{t_i} | i \in \mathcal{U}))$$

$$\text{Enc}(m, A, PP): s \leftarrow \mathbb{Z}_p, E = (A, E' = mY^s, (E_i = T_i^s = g^{t_i s} | i \in A), g^s)$$

$$\text{KeyGen}(\mathcal{C}, \text{MSK}): y \xrightarrow{\text{Sharing}} y_1, \dots, y_n, D = (D_i = g^{y_i/t_i} | i \in \mathcal{U})$$

$$\text{Dec}(E, D): \text{compute } Y^s = e(g, g)^{y^s} \text{ (} y \text{ is a linear combination of shares)}$$

Works only for Boolean formulas !

Secret Sharing and KP-ABE

Extension to Boolean Circuits. The Backtracking Attack

Solutions to the Backtracking Attack

1 Based on **multilinear maps**

- 1 Garg et al.: *Attribute-based Encryption for Circuits from Multilinear Maps*, CRYPTO 2013

2 Based on **integer lattices**

- 1 Gorbunov et al.: *Attribute-based Encryption for Circuits*, STACS 2013
- 2 Boneh et al.: *Attribute-based Encryption for Arithmetic Circuits*, Cryptology ePrint Archive 2013: 669
- 3 Boneh et al.: *Fully Key-homomorphic Encryption, Arithmetic Circuit ABE, and Compact Garbled Circuits*, EUROCRYPT 2014

Can it be done using only bilinear maps ? Garg et al. conjectured “No”

Progress: “F.L. Tiplea, C.C. Drăgan: Key-policy ABE for Boolean Circuits from Bilinear Maps, BCS 2014”

Quick Review of Garg et al.'s Solution

- 1 Uses **leveled multilinear maps**, which consists of:
 - 1 k groups G_1, \dots, G_k of prime order p , where $k - 1$ is the circuit depth;
 - 2 k generators g_1, \dots, g_k of these groups
 - 3 A set $\{e_{i,j} : G_i \times G_j \rightarrow G_{i+j} | i, j \geq 1, i + j \leq k\}$ of bilinear maps satisfying

$$e_{i,j}(g_i^a, g_j^b) = g_{i+j}^{ab}$$

- 2 Two keys are associated to each input wire
- 3 Three keys are associated to each AND-gate
- 4 Four keys are associated to each OR-gate
- 5 The circuit is evaluated bottom-up and the values associated to output wires of gates on level j are powers of g_{j+1}
- 6 $e_{i,j}$ works only in the “forward” direction

Our Construction

Basic elements of our construction:

- 1 Gates of fan-out greater than 1 are split into two gates;
- 2 Different secret sharing procedure;
- 3 Reconstruction based on chained multi-linear maps.

Translation into Graded Encoding Systems (GES)

Direct translation into the CLT (Coron, Lepoint, Tibouchi) GES (CRYPTO 2015):

- For each integer associated to an input wire, the sampling procedure outputs a level-0 encoding;
- For each FO-level key or FO-gate public key, the sampling procedure outputs a level-1 encoding;

Selective Security for KP-ABE

The adversary's advantage in the following game is negligible:

Init: adversary announces the set A of attributes

Setup: adversary receives PP

Phase 1: oracle access to the decryption key generation oracle (for Boolean circuits \mathcal{C} with $\mathcal{C}(A) = 0$)

Challenge: adversary submits two equally length messages m_0 and m_1 and receives the ciphertext associated to A and one of the two messages, say m_b

Phase 2: oracle access to the decryption key generation oracle (with the same constraint as above)

Guess: adversary outputs a guess $b' \leftarrow \{0, 1\}$

Security in the Selective Model

Decisional MDH problem in $\mathbf{e} = \{e_{i,j} : G_i \times G_j \rightarrow G_{i+j}, i + j \leq k\}$:

Instance: $(g_1, g_1^s, g_1^{c_1}, \dots, g_1^{c_k}, z)$, where $\langle g_1 \rangle = G_1$ and
 $s, c_1, \dots, c_k, z \leftarrow \mathbb{Z}_p$

Question: distinguish between $g_k^{sc_1 \dots c_k}$ and g_k^z

Decisional MDH assumption: no PPT algorithm can solve the DMDH problem with more than a negligible advantage

Theorem 1

The KP-ABE_Scheme is secure in the selective model under the decisional multi-linear Diffie-Hellman assumption.

Complexity and Comparisons

Boolean circuits with <ul style="list-style-type: none"> – n_1 input gates of fan-out 1 – n_2 input gates of fan-out > 1 – q_1 logic gates of fan-out > 1 – q_2 logic gates of fan-out > 1 – r FO-levels and depth ℓ 	No of keys	Multi-linear map (type, size, and mult. depth)
Garg et al.'s KP-ABE scheme	$2(n_1 + n_2) + 3(q_1 + q_2) \leq$ $\text{no. keys} \leq$ $2(n_1 + n_2) + 4(q_1 + q_2)$	<ul style="list-style-type: none"> • leveled • $\frac{\ell(\ell + 1)}{2}$ • $\ell + 1$
Our KP-ABE scheme	$n_2 + q_1 + q_2 + 3 \leq$ $\text{no. keys} \leq$ $n_2 + q_1 + 2q_2 + 2$	<ul style="list-style-type: none"> • chained • $r + 1 < \ell$ • $r + 1$

Conclusions

- We have proposed a KP-ABE scheme for general Boolean circuits, based on secret sharing and chained multi-linear maps;
- Our scheme associates exactly one key to each input, each FO-level, and each FO-gate output;
- The scheme is more efficient than Grag et al.'s scheme based on leveled multi-linear maps.

Finding an ABE scheme with just one bilinear map and efficient for all Boolean circuits still remains an open problem (it might not be possible !)
