**Svetlana Gorokhova**

Institut VNC, Vladikavkaz, Russia

Recall that an operator  $T: X \rightarrow F$  is called semi-compact if it takes bounded sets of  $X$  onto almost order bounded subsets of  $F$ . Compact operators are semi-compact. Alternatively,  $T$  is semi-compact if for each  $\varepsilon > 0$ , there exists  $u \in F^+$  such that  $T(B_X) \subseteq [-u, u] + \varepsilon B_F$ .

An operator  $T: E \rightarrow X$  is called  $M$ -weakly compact if  $\|Tx_n\| \rightarrow 0$  for each disjoint bounded sequence  $(x_n)$  in  $E$ .

An operator  $T: X \rightarrow E$  is called  $L$ -weakly compact if  $\|y_n\| \rightarrow 0$  for each disjoint sequence  $(y_n)$  in the solid hull of  $T(B_X)$ .

A Banach lattice  $E$  has property (d) if  $\|f_n\| \rightarrow 0$  for every disjoint weak\* null sequence  $(f_n)$  in  $E^*$ . If  $E$  is a  $\sigma$ -Dedekind complete Banach lattice, then  $E$  has (d). If  $E^*$  has weak\* sequentially continuous lattice operations then  $E$  has (d).  $L^p[0,1]$ ,  $1 \leq p \leq \infty$  has (d) whereas  $C[0,1]$  does not have (d) see Example 2.2:3 in [3].

$T: X \rightarrow F$  is called almost L-weakly compact (aLwc) if it maps relatively weakly compact subsets of  $X$  onto L-weakly compact subsets in  $F$ . Or  $f_n(Tx_n) \rightarrow 0$  for each disjoint bounded  $(f_n)$  in  $F^*$  and weakly null  $(x_n)$  in  $B_E$  and  $T(X) \subseteq F^a$ .

$T: E \rightarrow X$  is called almost M-weakly compact (aMwc) if for each disjoint sequence  $(x_n)$  in  $B_E$  and weakly null  $(f_n)$  in  $X^*$ ,  $f_n(Tx_n) \rightarrow 0$ .

aMwc operators contain M-weakly compact operators.  $Id$  of  $l^\infty$  is aMwc but it is not M-weakly compact.

Order intervals of  $E$  are limited if and only if lattice operations in  $E^*$  are weak\*sequentially continuous.

A norm bounded subset  $A$  of  $X$  is limited iff  $f_n(a_n) \rightarrow 0$  for all weak\* null  $(f_n)$  in  $X^*$  and all  $(a_n)$  in  $A$ .

Compact subsets in  $X$  are limited. If each limited subset of  $X$  is relatively compact then  $X$  is said to be a Gelfand-Phillips (GP-space, for short). Reflexive spaces, separable spaces,  $\sigma$ -Dedekind complete Banach lattices with order continuous norms are GP-spaces.  $l^1$  and  $c_0$  are GP-spaces but  $l^\infty$  is not. Order intervals of a Banach lattice are not necessarily limited sets. For example the interval  $[-1,1]$  in  $c$  is not limited

If  $F$  is a KB-space, then for every Banach lattice  $E$  where  $E^*$  has PSP, each regular operator is M and L- weakly compact.(Theorem 3.8)

If  $E^*$  is a KB-space, then for every Banach lattice  $F$  with PSP every regular operator  $T:E \rightarrow F$  is M and L-weakly compact.(Theorem 3.8)

Assertion 1) If  $F$  is discrete with order continuous norm, then every regular Mwc  $T: E \rightarrow X$  is compact. (Theorem 3.4)

If  $E^*$  is discrete with order continuous norm, then every regular Lwc operator  $T: E \rightarrow F$  is compact (Theorem 4.2)

If  $Y$  contains  $c_0$ , then every Mwc  $T: E \rightarrow Y$  is compact iff  $(E^*)^a$  is discrete.

An operator  $T: X \rightarrow Y$  is called limited if  $T(B_X)$  is a limited subset of  $Y$ .  $T: X \rightarrow E$  is called almost limited if  $T(B_X)$  is almost limited in  $E$ . The embedding of  $c_0$  into  $l^\infty$  is limited, but not compact. The closed unit ball of  $l^\infty$  is almost limited. Phillip's lemma (Theorem 54.67 [2]) says closed unit ball of  $c_0$  is limited in  $l^\infty$

Let  $T: X \rightarrow F$  and suppose  $F$  has order continuous norm. If  $T$  is limited then it is L-weakly compact and therefore is weakly compact and semi-compact.

The adjoint  $T^*$  is almost Dunford-Pettis and order weakly compact. If  $F^*$  has weak\* continuous lattice operations, then limited operators is an order ideal in L-weakly compact operators.

## THE EFFECT OF WEAK\* CONTINUITY OF LATTICE OPERATIONS IN THE DUAL

A operator  $T:X \rightarrow F$  is called limitedly  $L$ -weakly compact ( $l$ -Lwc) if  $T$  maps limited subsets of  $X$  onto  $L$ -weakly compact subsets of  $F$ .

$l$ -Lwc operators were defined and studied in [3]. An operator  $T$  is  $l$ -Lwc if and only if  $T^* f_n \rightarrow 0$  in weak\* topology of  $X^*$  for each bounded disjoint  $(f_n)$  by Lemma 2.3.1. in [3].

*Let  $T:X \rightarrow F$  be a semi-compact operator:*

- *If  $F$  has limited order intervals, then  $T$  is limited.*
- *If  $F$  has almost limited intervals, then  $T$  is almost limited.*
- *If  $F$  has compact order intervals, then  $T$  is compact.*
- *If  $F$  has order continuous norm, then  $T$  is weakly compact*

It follows that L-weakly compact, order bounded M-weakly compact, and operators dominated by semi-compact operators taking values in a Riesz space with limited order intervals are limited operators as each of these operators are semi-compact. See Prop.2.1. in [5].

A semi-compact operator need not be compact, weakly compact, L or M-weakly compact. The identity of  $l^\infty$  is semi-compact but it does not have any of the compactness properties mentioned.

*Let  $T: E \rightarrow F$  be a semi-compact operator. If  $F$  has limited order intervals and order continuous norm, then  $T$  is compact.*

Let  $E$  have limited order intervals and  $F$  have order continuous norm and let  $T$  be a regular semi-compact operator  $E \rightarrow F$ , then  $T$  is AM-compact.

Let  $T: E \rightarrow X$  be a weakly compact operator. If  $E$  has limited order intervals then  $T$  is AM-compact

Let us note that not every weakly compact operator is AM-compact. The identity of  $L^2[0,1]$  is weakly compact but it is not AM-compact.

Suppose  $E$  has limited order intervals. Let  $T: E \rightarrow X$  be order weakly compact, then  $T$  is AM-compact

*Suppose  $E^*$  has order continuous norm and  $E$  has limited order intervals and  $F$  has PSP, then every order bounded weakly compact operator  $T: E \rightarrow F$  is limited.*

Proof. Since  $F$  has PSP,  $F$  has order continuous norm. As  $E^*$  and  $F$  has order continuous norms an order bounded  $T: E \rightarrow F$  is compact if and only if  $T$  is semi-compact and AM compact by Theorem 125.5 in [22]. Let  $T: E \rightarrow F$  be a weakly compact operator. Then  $T$  is AM compact by Proposition 2.2. above. On the other hand  $T$  is  $M$ -weakly compact by Theorem 3.3 in [11]. As order bounded  $M$ -weakly compact operators are semi-compact,  $T$  is semi-compact and therefore compact. ■

*Suppose  $E^*$  has order continuous norm and  $F^*$  has weak\* continuous lattice operations, then each positive  $aDP$  operator is limited.*

*Suppose  $E^*$  has weak\* sequentially continuous lattice operations, then each Mwc operator  $T: E \rightarrow F$  is limited.*

Proof. Let  $(f_n)$  be a weak\* null sequence in  $F^*$ . We need to show  $\|T^*(f_n)\| \rightarrow 0$ . For this it suffices to show  $|T^*(f_n)| \rightarrow 0$  in  $\sigma(E^*, E)$  and  $T^*(f_n)(x_n) \rightarrow 0$  for each norm bounded disjoint sequence  $(x_n)$  in  $E_+$ . Since  $T$  is bounded  $(T^*f_n) \rightarrow 0$  in  $\sigma(E^*, E)$ . Continuity of lattice operations in  $E^*$  gives us  $|T^*f_n| \rightarrow 0$  in  $\sigma(E^*, E)$ .

$$|T^*(f_n)(x_n)| = |f_n(Tx_n)| \leq \|f_n\| \|Tx_n\|$$

Since  $(f_n)$  is norm bounded and  $T$  is Mwc, The claim follows. ■

*If every positive limited operator  $T: E \rightarrow F$  is Mwc, then  $E^*$  is a KB space.*

Proof. Assume  $E^*$  does not have order continuous norm. Then there exists an order bounded disjoint sequence in  $E^*$  such that  $(f_n) \subseteq [0, f]$  which does not converge to zero in norm. Choose  $y \in F_+$  such that  $\|y\| = 1$  and a functional  $g \in F^*$  with  $\|g\| = 1$  and  $g(y) = \|g\| = 1$ . Define  $T: E \rightarrow F$  by  $T(x) = g(x)y$  for  $x \in E$ . As  $T$  is compact, it is limited. We claim  $T$  is not Mwc. For this it is enough to show  $T^*$  is not Lwc. Let us observe that  $T^*(h) = h(y)f$ . Taking  $h=g$ , we see that  $T^*g = f$ . So that the sequence  $(f_n)$  is a sequence in the solid hull of  $T^*(B_F)$ . This shows that  $T^*$  is not Lwc and therefore  $T$  is not Mwc. ■

*If Dunford-Pettis operators from  $E$  to  $F$  are limited, then one of  $E^*$  has order continuous norm, or order bounded subsets of  $F$  are limited holds.*

*If every weakly compact  $T: E \rightarrow X$  is limited, then one of the following holds:*

- $X$  has the Dunford-Pettis property,*
- $E^*$  has order continuous norm,*

*If each semi-compact operator  $T: X \rightarrow F$  is aLwc for every  $X$  then  $F$  has order continuous norm.*

*Each limited operator  $T: E \rightarrow F$  is aLwc if and only if  $F$  has order continuous norm.*

*1) If each limited operator  $T: E \rightarrow F$  is aMwc then,  $E^*$  has order continuous norm.*

*2) If  $E^*$  has order continuous norm, then each regular  $T: E \rightarrow F$  limited operator is aMwc.*

*If  $E$  has order continuous norm and limited order intervals, then  $T^2$  is compact for each positive semi-compact operator on  $E$ .*

*Suppose  $E$  has limited order intervals and  $T: E \rightarrow E$  be semi-compact and weakly compact. Then  $T^2$  compact.*

an operator  $T: E \rightarrow F$  is called limitedly  $M$ -weakly compact if, each bounded disjoint sequence  $(x_n)$  in  $E$ ,  $(Tx_n)$  is weakly null.

*Suppose  $F$  has Schur property, then  $l\text{-Mwc}(E, F) \subseteq W_o(E, F)$ .*

Proof. Let  $T \in l\text{-Mwc}$ . We need to show

$\|Tx_n\| \rightarrow 0$  for each order bounded disjoint sequence  $(x_n)$  in  $E$ .  $(x_n)$  is weakly null as it is order bounded and disjoint. Thus,  $(x_n)$  is bounded, as  $T$  is  $l\text{-Mwc}$ ,  $(Tx_n)$  is weakly null and therefore norm null by the Schur property of  $F$ . ■

## ALMOST LIMITED OPERATORS

Recall that  $E$  has positive disjoint Schur property (PDSP) if every positive disjoint weak\* null sequence in the dual is norm null. It follows that whenever  $E$  has PDSP then every bounded operator into  $E$  is almost limited. Also notice that since each  $L$ -weakly compact set in a Banach lattice is almost limited by Theorem 2.6. in [10], each  $L$ -weakly compact operator  $T: X \rightarrow E$  is almost limited.

Recall that a Banach lattice is said to have weak Dunford-Pettis\* Property (wDP\*P, for short) if every relatively weakly compact set is almost limited. if  $E$  has wDP\*property then each weakly compact operator  $T: X \rightarrow E$  is almost limited. In particular, every  $L$  and  $M$ -weakly compact operator is almost limited.

The identity of  $l^\infty$  is almost limited but it is not limited as the closed unit ball of  $l^\infty$  is not a limited set.

*If  $F$  has dual disjoint Schur property then, each bounded operator  $T:E \rightarrow F$  is almost limited.*

*If  $F$  has (d) then, each regular Mwc  $T:E \rightarrow F$  is almost limited.*

Let  $(f_n)$  be a disjoint weak\* null sequence in  $E^*$ . By the (d) property of  $F$ ,  $(|f_n|) \rightarrow 0$  is also weak\* null in  $F^*$ . As  $|T^*f_n| \leq T^*|f_n|$  the sequence  $(|T^*f_n|)$  is also weak\* null in  $E^*$ . Thus to show  $\|T^*f_n\| \rightarrow 0$ , it suffices to show  $T^*f_n(x_n) \rightarrow 0$  for each disjoint bounded sequence  $(x_n)$  in  $E_+$ . Consider

$$|T^*f_n(x_n)| = |f_n(Tx_n)| \leq \|f_n\| \|Tx_n\|$$

Since  $\|f_n\| \leq N$  for some  $N$  and all  $n$ , and since  $\|Tx_n\| \rightarrow 0$  as  $T$  is Mwc, it follows that  $|T^*f_n(x_n)| \rightarrow 0$  and therefore  $\|T^*f_n\| \rightarrow 0$  and  $T$  is almost limited. ■

**Corollary** If  $E^*$  has positive Schur property, then for Banach lattice  $F$  with (d) each  $T:E \rightarrow F$  weakly compact is almost limited. ■

**Corollary** Suppose  $E^*$  has the PSP and  $F$  is a KB space. Then every regular  $T:E \rightarrow F$  is almost limited.

Proof. As they are  $L$  and  $M$  weakly compact operators. ■

*For a Banach lattice  $F$ , the following are equivalent;*

- $F$  has order continuous norm,*
- For every  $X$ , each almost limited operator  $T: X \rightarrow F$  is Lwc,*
- For every  $X$ , each limited operator  $T: X \rightarrow F$  is Lwc,*
- For every  $E$ , each positive rank one operator is Lwc.*

iv) implies i). For each  $y \in F_+$ , there exists a positive operator  $T: E \rightarrow F$  such that  $T(E) = \text{span}(y)$ , then by [3, Theorem 5.66],  $y \in F^a$ , and as  $y \in F_+$  is arbitrary, this implies that  $F = F^a$  and hence  $F$  has order continuous norm. ■

*Let  $F$  has positive Grothendieck property and has (d), then every  $\alpha$ Mwc operator is almost limited.*

*Suppose  $E$  has (d) and let  $T:E \rightarrow F$ . If  $T$  is both  $l$ -Lwc and Mwc, then  $T$  is almost limited.*

Proof. We need to show  $\|T^*f_n\| \rightarrow 0$  for each weak\* null disjoint sequence  $(f_n)$  in  $F^*$ . For this it suffices to show  $\|T^*f_n\| \rightarrow 0$  weak\* and  $(T^*f_n)(x_n) \rightarrow 0$  for each disjoint bounded sequence  $(x_n)$  in  $E_+$ . Since  $T$  is  $l$ -Lwc  $(T^*f_n)$  is weak\* null in  $E^*$ . Property (d) ensures that  $\|T^*f_n\| \rightarrow 0$  in weak\* topology. Since  $(f_n)$  is weak\* null, it is bounded and it follows from

$$|T^*(f_n)(x_n)| = |f_n(Tx_n)| \leq \|f_n\| \|Tx_n\|$$

As  $T$  is Mwc  $\|Tx_n\| \rightarrow 0$  and  $T^*(f_n)(x_n) \rightarrow 0$

*Suppose each positive weak Dunford-Pettis operator from  $E$  to  $F$  is Mwc and  $F$  is  $\sigma$ -Dedekind complete then one of  $E$  has positive Schur property or  $F$  has order continuous norm holds.*

*Let  $E, F$  be Banach lattices where  $E$  has almost- $DP^*$  property.  $F$  is  $\sigma$ -Dedekind complete and  $E^*$  has order continuous norm, then each regular operator  $T: E \rightarrow F$  is almost limited.*

**Corollary** Suppose  $E$  is a Banach lattice such that  $E^*$  has the PSP, then for each KB-space  $F$  and regular operator  $T: E \rightarrow F$ ,  $T$  is almost limited.

**Corollary.** Suppose  $F$  is a KB-space. Then for every Banach lattice  $E$  with  $E^*$  has PSP, every regular operator is almost limited.

**Corollary.** Suppose  $E^*$  is a KB-space, then for every Banach lattice with PSP, each regular operator is almost limited.

Every positive aDPO is almost limited iff  $F$  has DDSP or  $E^*$  has order continuous norm.

*Suppose  $F$  has (d) and DPSP (or equivalently  $F$  has DDSP) or  $E^*$  is KB, then each positive aLwc operator is almost limited.*

Not every almost limited operator is M-weakly compact. The identity on  $l^\infty$  is almost limited but it is neither M nor L-weakly compact

*Suppose  $E$  has order continuous norm and  $F$  has (d). If every positive almost limited operator  $T: E \rightarrow F$  is Mwc, then  $E^*$  and  $F$  have order continuous norms.*

*Almost limited operators are contained in aLwc  $(X, E)$  operators iff  $E$  has order continuous norm.*

*Each almost limited positive operator  $T: E \rightarrow F$  is aMwc iff  $E^*$  has order continuous norm.*

*Suppose  $E$  has order continuous norm and each positive weakly compact operator  $T: X \rightarrow E$  is almost limited. Then one of  $E$  is a KB-space or  $X$  has the Dunford-Pettis Property holds.*

*Let  $E$  and  $F$  be  $\sigma$ -Dedekind complete Banach lattices. If one of  $E$  or  $F$  has order continuous norm, then each almost limited  $T: E \rightarrow F$  is order weakly compact.*

*Suppose  $E^*$  and  $F$  have order continuous norms and  $E$  has the property that each bounded positive disjoint sequence in  $E$  is order bounded and  $E$  has limited order intervals. Then each regular operator  $T: E \rightarrow F$  is positively limited.*

*Let  $E$  be an AL-space and  $F$  be a Banach lattice with order continuous norm, then each almost limited operator  $T: E \rightarrow F$  has an almost limited modulus  $|T|$ .*

Proof. Since  $F$  has order continuous norm, almost limited  $T$  is L-weakly compact. Hence  $T$  has an L-weakly compact modulus  $|T|$  by Theorem 2.4. in [11]. Thus  $|T|$  is almost limited by Theorem 2.6 in [8].

It is well known that adjoints of almost limited operators are almost Dunford-Pettis and order weakly compact. On the other hand an almost limited operator itself need not be order weakly compact. For example the identity on  $l^\infty$  is almost limited but not order weakly compact. Duality of order weakly compact operators was studied in [6].

*Let  $E$  and  $F$  be  $\sigma$ -Dedekind complete Banach lattices. If one of  $E$  or  $F$  has order continuous norm, then each almost limited  $T:E \rightarrow F$  is order weakly compact.*

Proof. Let  $T:E \rightarrow F$  be almost limited. Then  $T^*$  is order weakly compact. Then  $T$  is also order weakly compact by Theorem 2.8 in [6]. ■

The following result was proved for order weakly compact operators  $T:E \rightarrow F$  where  $E$  has the property that each bounded disjoint sequence  $(x_n)$  is order bounded.

**Proposition 3.19.** Suppose  $E^*$  and  $F$  have order continuous norms and  $E$  has the property that each bounded positive disjoint sequence in  $E$  is order bounded and  $E$  has limited order intervals. Then each regular operator  $T:E \rightarrow F$  is almost limited.

Proof. The operator  $T$  admits a factorization over a Banach lattice  $G$  with  $G$  and  $G^*$  have order continuous norms, say  $T = SR$  where  $R$  and  $S$  are both positive. We claim  $R$  is positively limited. Let  $(z_n^*)$  be a positive weak\*-null sequence in  $E^*$  and  $(x_n)$  be a positive disjoint bounded sequence in  $E$ . By the assumption there exists  $x$  with  $0 \leq x_n \leq x$  for each  $n$ . As  $R$  is positive  $0 \leq Rx_n \leq Rx$ . Thus  $0 \leq R^*(z_n^*)(x_n) \leq (z_n^*)(Rx_n) \leq (z_n^*)(x)$  which shows  $R^*(z_n^*)(x_n) \rightarrow 0$ . By the Lemma we conclude that  $R$  is positively limited. Let  $(x_n^{**})$  be a positive weak\*-null sequence in  $E^{**}$   $(y_n^*)$  be a positive disjoint bounded sequence in  $F^*$ . Since  $F$  has order continuous norm,  $(y_n^*)$  is weak\*-null and hence  $R^*(y_n^*) \rightarrow 0$  in norm proving  $R$  is positive limited. It follows that  $T$  is almost limited as  $S$  is bounded. ■
